

Abstract

The sPHENIX detector at BNL's Relativistic Heavy Ion Collider (RHIC) will enable a spectrum of new or improved cold QCD measurements, enhancing our understanding of the initial state for nuclear collisions. sPHENIX measurements in proton-proton and proton-nucleus collisions will reveal more about how partons behave in a nuclear environment, inform our understanding of the initial state in heavy-ion collisions, and provide comparative data to investigate modification of fragmentation functions. Measurements will also take advantage of RHIC's unique capability to collide polarized protons on nuclei, which provides novel opportunities to study nuclear effects with spin observables. The cold QCD nuclear physics program for the sPHENIX midrapidity detector will be presented.

How might collective and many-body behavior arise or evolve from small to large systems?

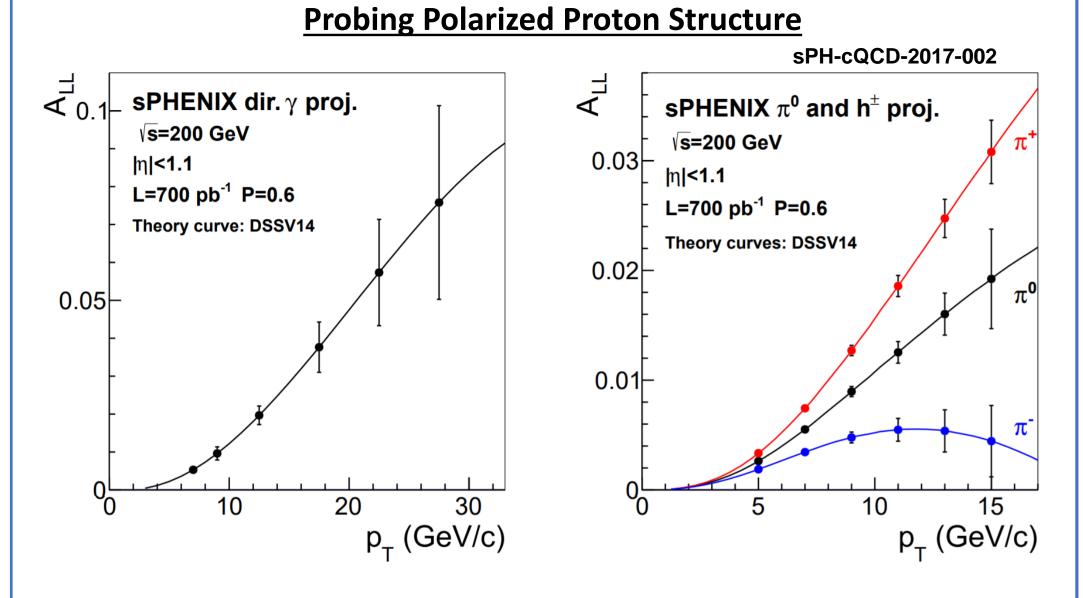

With the EIC on the horizon, the window for exploring the relationships between (polarized) p+p and p+A collisions can be exploited with the sPHENIX detector. These studies will permit an EIC experiment to address universality between p+A and e+A collisions.

Expected uncertainties on Double-Helicity Asymmetry (A_{LL}) measurements for (Left) direct photon production $(qg \rightarrow q\gamma)$ and (Right) hadron production projected onto respective DSSV predictions. These uncertainties are reduced in comparison to previous measurements and are expected to reduce the gluon helicity PDF (ΔG) uncertainty significantly in the region of 0.05 < x < 0.4.

Cold QCD Physics with sPHENIX
